

## Synoptic Meteorology II: Isentropic Analysis Exercise

Due: 7 April 2015, at the start of class

In Figure 1, you are given an analysis of pressure (hPa; contoured), wind (barbs; half-flag: 5 kt, flag: 10 kt, pennant: 50 kt), and mixing ratio ( $\text{g kg}^{-1}$ ; shaded) on the 300 K isentropic surface. In Figure 2, you are given the same analysis of pressure and mixing ratio, but now the wind that is displayed is the storm-relative wind (i.e., with the motion of the mid-latitude cyclone being analyzed subtracted from the full wind).

- a. On Figure 1, using the principles of isentropic analysis developed in class, please *shade* areas of isentropic ascent and *crosshatch* areas of isentropic descent.
- b. Where do you believe the strongest ascent to be located? Why?
- c. Where do you believe the strongest descent to be located? Why?
- d. How do the locations and/or magnitudes of ascent and descent change when the storm-relative wind is considered in place of the full wind?
- e. Which analysis – using the full wind or the storm-relative wind – provides better overlap between the wind and mixing ratio fields? What caused you to answer as you did?

pressure (contour, hPa), wind (barb, half-flag: 5 kt, flag: 10 kt, pennant: 50 kt), and mixing ratio (shaded,  $\text{g kg}^{-1}$ ) on the 300 K isentropic surface

**Figure 1.** Pressure (hPa; contours), wind (barbs; half-flag: 5 kt, flag: 10 kt, pennant: 50 kt), and mixing ratio ( $\text{g kg}^{-1}$ ; shaded) on the 300 K isentropic surface valid at 1800 UTC 4 March 1976.

pressure (contour, hPa), storm-rel. wind (half-flag: 5 kt, flag: 10 kt, pennant: 50 kt), and mixing ratio (shaded,  $\text{g kg}^{-1}$ ) on the 300 K isentropic surface

**Figure 2.** As in Figure 1, except for the storm-relative wind instead of the full wind.
